CONCLUSIONS

• The impact of OIC, the effectiveness of laxative treatment, and the adverse effect of OIC on the effectiveness of pain control are all perceived differently by patients versus HCPs.

• These disparate perceptions between patient and HCP regarding the importance and severity of OIC complicate management and demonstrate a need for greater communication.

• Clinical education and coordination of care by HCPs, including nursing professionals, may help to address the need to better appreciate and proactively manage the burden of OIC in patients with chronic noncancer pain.
